# Preface

Welcome to the SC14 IAR Assembler Reference Guide. The purpose of this guide is to provide you with detailed reference information that can help you to use the SC14 IAR Assembler for creating DIP or GenDSP output for the SC14 co-processor.

---

## Who should read this guide

You should read this guide if you plan to develop an application using assembler language for the SC14 co-processor and need to get detailed reference information on how to use the SC14 IAR Assembler. In addition, you should have a working knowledge of the following:

- The architecture and instruction set of the SC14xxx co-processor. Refer to the documentation from National Semiconductor for information about the SC14xxx co-processor.
- General assembler language programming.
- Application development for embedded systems.
- The operating system of your host machine.

---

## How to use this guide

When you first begin using the SC14 IAR Assembler, you should read the *Introduction to the SC14 IAR Assembler* chapter in this reference guide.

If you are an intermediate or advanced user, you can focus more on the reference chapters that follow the introduction.

If you are new to using the IAR toolkit, we recommend that you first read the initial chapters of the *CR16C IAR Embedded Workbench™ IDE User Guide*. They give product overviews, as well as tutorials that can help you get started.

---

## What this guide contains

Below is a brief outline and summary of the chapters in this guide.

- *Introduction to the SC14 IAR Assembler* provides programming information. It also describes the source code format, and the format of assembler listings.
- *Assembler options* first explains how to set the assembler options from the command line and how to use environment variables. It then gives an alphabetical summary of the assembler options, and contains detailed reference information about each option.

- *Assembler operators* gives a summary of the assembler operators, arranged in order of precedence, and provides detailed reference information about each operator.
- *Assembler directives* gives an alphabetical summary of the assembler directives, and provides detailed reference information about each of the directives, classified into groups according to their function.
- *Assembler diagnostics* contains information about the formats and severity levels of diagnostic messages.

---

## Other documentation

The complete set of IAR Systems development tools for the SC14xxx co-processor is described in a series of guides. For information about:

- Using the IAR Embedded Workbench™ and the IAR C-SPY™ Debugger, refer to the *CR16C IAR Embedded Workbench™ IDE User Guide*
- Using the IAR XLINK Linker™ and the IAR XLIB Librarian™, refer to the *IAR XLINK Linker™ and IAR XLIB Librarian™ Reference Guide*.

All of these guides are delivered in PDF format on the installation media. Some of them are also delivered as printed books.

---

## Document conventions

This guide uses the following typographic conventions:

Style	Used for
computer	Text that you enter or that appears on the screen.
<i>parameter</i>	A label representing the actual value you should enter as part of a command.
[option]	An optional part of a command.
{a   b   c}	Alternatives in a command.
<b>bold</b>	Names of menus, menu commands, buttons, and dialog boxes that appear on the screen.
<i>reference</i>	A cross-reference within or to another part of this guide.
	Identifies instructions specific to the versions of the IAR Systems tools for the IAR Embedded Workbench interface.
	Identifies instructions specific to the command line versions of IAR Systems development tools.

Table 1: Typographic conventions used in this guide

# Introduction to the SC14 IAR Assembler

This chapter describes the source code format for the SC14 IAR Assembler. Refer to National Semiconductor's hardware documentation for syntax descriptions of the instruction mnemonics.

---

## Source format

The format of an assembler source line is as follows:

```
[label [:]] [operation] [operands] [; comment]
```

where the components are as follows:

<i>label</i>	A label, which is assigned the value and type of the current program location counter (PLC). The : (colon) is optional if the label starts in the first column.
<i>operation</i>	An assembler instruction or directive. This must not start in the first column.
<i>operands</i>	An assembler instruction can have zero, one, or two operands.  The data definition directives, for example DB and DC8, can have any number of operands. For reference information about the data definition directives, see <i>Data definition or allocation directives</i> , page 66.
<i>comment</i>	Comment, preceded by a ; (semicolon).

The fields can be separated by spaces or tabs.

A source line may not exceed 2047 characters.

Tab characters, ASCII 09H, are expanded according to the most common practice; i.e. to columns 8, 16, 24 etc.

The SC14 IAR Assembler uses the default file extensions `s44`, `asm`, and `msa` for source files. **Note:** The file extension for object files is `r45`, which corresponds to the file extension for CR16C object files.

---

## Assembler expressions

Expressions can consist of operands and operators.

The assembler will accept a wide range of expressions, including both arithmetic and logical operations. All operators use 32-bit two's complement integers, and range checking is only performed when a value is used for generating code.

Expressions are evaluated from left to right, unless this order is overridden by the priority of operators; see also *Precedence of operators*, page 21.

The following operands are valid in an expression:

- User-defined symbols and labels.
- Constants, excluding floating-point constants.
- The program location counter (PLC) symbol, \$.

These are described in greater detail in the following sections.

The valid operators are described in the chapter *Assembler operators*, page 21.

### TRUE AND FALSE

In expressions a zero value is considered FALSE, and a non-zero value is considered TRUE.

Conditional expressions return the value 0 for FALSE and 1 for TRUE.

### USING SYMBOLS IN RELOCATABLE EXPRESSIONS

Expressions that include symbols in relocatable segments cannot be resolved at assembly time, because they depend on the location of segments.

Such expressions are evaluated and resolved at link time, by the IAR XLINK Linker™. There are no restrictions on the expression; any operator can be used on symbols from any segment, or any combination of segments.

### SYMBOLS

User-defined symbols can be up to 255 characters long, and all characters are significant.

Symbols must begin with a letter, a–z or A–Z, ? (question mark), or \_ (underscore). Symbols can include the digits 0–9 and \$ (dollar).

For built-in symbols like instructions, registers, operators, and directives case is insignificant. For user-defined symbols case is by default significant but can be turned on and off using the `-s` assembler option. See page 17 for additional information.

## LABELS

Symbols used for memory locations are referred to as labels.

### Program location counter (PLC)

The program location counter is called \$. For example:

```
JMP $ ; Loop forever
```

## INTEGER CONSTANTS

Since all IAR Systems assemblers use 32-bit two's complement internal arithmetic, integers have a (signed) range from -2147483648 to 2147483647.

Constants are written as a sequence of digits with an optional - (minus) sign in front to indicate a negative number.

Commas and decimal points are not permitted.

The following types of number representation are supported:

Integer type	Example
Binary	1010b, b'1010'
Octal	1234q, q'1234'
Decimal	1234, -1, d'1234'
Hexadecimal	0FFFFh, 0xFFFF, h'FFFF'

Table 2: Integer constant formats

**Note:** Both the prefix and the suffix can be written with either uppercase or lowercase letters.

## ASCII CHARACTER CONSTANTS

ASCII constants can consist of between zero and more characters enclosed in single or double quotes. Only printable characters and spaces may be used in ASCII strings. If the quote character itself is to be accessed, two consecutive quotes must be used:

Format	Value
'ABCD'	ABCD (four characters).
"ABCD"	ABCD^0' (five characters the last ASCII null).
'A"B'	A' B
'A'''	A'
'''' (4 quotes)	'

Table 3: ASCII character constant formats

Format	Value
' ' (2 quotes)	Empty string (no value).
""	Empty string (an ASCII null character).
'\'	'
\"	\

Table 3: ASCII character constant formats (Continued)

## PREDEFINED SYMBOLS

The SC14 IAR Assembler defines a set of symbols for use in assembler source files. The symbols provide information about the current assembly, allowing you to test them in preprocessor directives or include them in the assembled code. The strings returned by the assembler are enclosed in double quotes.

The following predefined symbols are available:

Symbol	Value
__DATE__	Current date in dd/Mmm/yyyy format (string).
__FILE__	Current source filename (string).
__IAR_SYSTEMS_ASM__	IAR assembler identifier ( 0x01).
__LINE__	Current source line number (number).
__TID__	Target identity, consisting of two bytes (number). The high byte is the target identity, which is 45 for ASC14. The low byte is the processor option *16.
__TIME__	Current time in hh:mm:ss format (string).
__VER__	Version number in integer format; for example, version 4.17 is returned as 417 (number).

Table 4: Predefined symbols

## Including symbol values in code

To include a symbol value in the code, you use the symbol in one of the data definition directives.

For example, to include the time of assembly as a string for the program to display:

```
tim    DC8    __TIME__, ", ", __DATE__, 0; time and date
```

## Testing symbols for conditional assembly

To test a symbol at assembly time, you use one of the conditional assembly directives.

---

## Programming hints

This section gives hints on how to write efficient code for the SCI4 IAR Assembler.

### PROCESSOR-SPECIFIC FILES

In the previous DIP IAR Assembler, ADIP, the environment variable `QDIPINFO` was used to point out the `*.chp` files from which the assembler reads opcode information. This variable is no longer used. Instead, the information about the `*.chp` file location is entered in the registry when you install the product.

The ADIP assembler generated an output where each byte in a word was swapped. Since no DIP application was programmed using a normal programming tool, this error was never discovered. When adding the GenDSP format, the error was found and corrected. If old DIP programs are to be used in the new environment, without being recompiled, this needs to be taken in consideration.

When using direct jumps in the old ADIP environment, byte addresses were used, for example:

```
JMP 0x24
```

These were later solved by the linker to give the DIP a word address.

The ASC14 assembler uses word addresses directly, for example:

```
JMP 0x12
```

### USING C-STYLE PREPROCESSOR DIRECTIVES

The C-style preprocessor directives are processed before other assembler directives. Therefore, do not use preprocessor directives in macros and do not mix them with assembler-style comments.

---

## Output formats

The relocatable and absolute output is in the same format for all IAR assemblers, because object code is always intended for processing with the IAR XLINK Linker.

In absolute formats the output from XLINK is, however, normally compatible with the chip vendor's debugger programs (monitors), as well as with PROM programmers and stand-alone emulators from independent sources.

# Assembler options

This chapter first explains how to set the options from the command line, and gives an alphabetical summary of the assembler options. It then provides detailed reference information for each assembler option.

The *CRI6C IAR Embedded Workbench™ IDE User Guide* describes how to set assembler options in the IAR Embedded Workbench, and gives reference information about the available options.

---

## Setting command line options

To set assembler options from the command line, you include them on the command line, after the `asc14` command:

```
asc14 [options] [sourcefile] [options]
```

These items must be separated by one or more spaces or tab characters.

If all the optional parameters are omitted the assembler will display a list of available options a screenful at a time. Press Enter to display the next screenful.

For example, when assembling the source file `tutor.s44`, use the following command to generate a list file to the default filename (`tutor.lst`):

```
asc14 tutor -L
```

Some options accept a filename, included after the option letter with a separating space. For example, to generate a list file with the name `list.lst`:

```
asc14 tutor -l list.lst
```

Some other options accept a string that is not a filename. This is included after the option letter, but without a space. For example, to generate a list file to the default filename but in the subdirectory named `list`:

```
asc14 tutor -Llist\
```

**Note:** The subdirectory you specify must already exist. The trailing backslash is required because the parameter is prepended to the default filename.

### EXTENDED COMMAND LINE FILE

In addition to accepting options and source filenames from the command line, the assembler can accept them from an extended command line file.

Extended command line files have the default extension `.xcl`, and can be specified using the `-f` command line option. For example, to read the command line options from `extend.xcl`, enter:

```
asc14 -f extend.xcl
```

### Error return codes

When using the SC14 IAR Assembler from within a batch file, you may need to determine whether the assembly was successful in order to decide what step to take next. For this reason, the assembler returns the following error return codes:

Return code	Description
0	Assembly successful, warnings may appear
1	There were warnings (only if the <code>-ws</code> option is used)
2	There were errors

*Table 5: Assembler error return codes*

### ASSEMBLER ENVIRONMENT VARIABLES

Options can also be specified using the `ASMSC14` environment variable. The assembler appends the value of this variable to every command line, so it provides a convenient method of specifying options that are required for every assembly.

The following environment variable can be used with the SC14 IAR Assembler:

Environment variable	Description
<code>ASC14_INC</code>	Specifies directories to search for include files; for example: <code>set ASC14_INC=c:\myinc\</code>
<code>ASMSC14</code>	Specifies command line options; for example: <code>set ASMSC14=-L -ws</code>

*Table 6: Assembler environment variables*

For example, setting the following environment variable will always generate a list file with the name `temp.lst`:

```
ASMSC14=-l temp.lst
```

## Summary of assembler options

The following table summarizes the assembler options available from the command line:

Command line option	Description
-B	Macro execution information
-b	Makes a library module
-c [DEAOM]	Conditional list
-Dsymbol [=value]	Defines a symbol
-Enumber	Maximum number of errors
-f extend.xcl	Extends the command line
-G	Opens standard input as source
-Iprefix	Includes paths
-i	#included text
-L[prefix]	Lists to prefixed source name
-l filename	Lists to named file
-Mab	Macro quote characters
-N	Omits header from assembler listing
-Oprefix	Sets object filename prefix
-o filename	Sets object filename
-plines	Lines/page
-r{e n}	Generates debug information
-S	Sets silent operation
-s{+ -}	Case sensitive user symbols
-tn	Tab spacing
-Usymb	Undefines a symbol
-vSC14xxx	Specifies target processor
-w[string] [s]	Disables warnings
-x [DI2]	Includes cross-references

Table 7: Assembler options summary

---

## Descriptions of assembler options

The following sections give full reference information about each assembler option.

---

**-B -B**

Use this option to make the assembler print macro execution information to the standard output stream on every call of a macro. The information consists of:

- The name of the macro
- The definition of the macro
- The arguments to the macro
- The expanded text of the macro.

This option is mainly used in conjunction with the list file options `-L` or `-l`; for additional information, see page 13.

This option is identical to the **Macro execution info** option in the **ASC14** category in the IAR Embedded Workbench.

---

**-b -b**

This option causes the object file to be a library module rather than a program module.

By default the assembler produces a program module ready to be linked with the IAR XLINK Linker. Use the `-b` option if you instead want the assembler to make a library module for use with XLIB.

If the `NAME` directive is used in the source (to specify the name of the program module), the `-b` option is ignored, i.e. the assembler produces a program module regardless of the `-b` option.

This option is identical to the **Make a LIBRARY module** option in the **ASC14** category in the IAR Embedded Workbench.

---

**-c -c [DEAOM]**

Use this option to control the contents of the assembler list file. This option is mainly used in conjunction with the list file options `-L` and `-l`; see page 13 for additional information.

The following table shows the available parameters:

Command line option	Description
-cA	Assembled lines only
-cD	Disable list file
-cE	No macro expansions
-cM	Macro definitions
-cO	Multiline code

Table 8: Conditional list (-c)

This option is related to the **List file** options in the **ASC14** category in the IAR Embedded Workbench.

---

**-D** *Dsymbol* [=value]

Use this option to define a preprocessor symbol with the name *symbol* and the value *value*. If no value is specified, 1 is used.

The **-D** option allows you to specify a value or choice on the command line instead of in the source file.

### Example

For example, you could arrange your source to produce either the test or production version of your program dependent on whether the symbol `testver` was defined. To do this, use include sections such as:

```
#ifdef testver
... ; additional code lines for test version only
#endif
```

Then select the version required in the command line as follows:

```
Production version:   asc14 prog
Test version:         asc14 prog -Dtestver
```

Alternatively, your source might use a variable that you need to change often. You can then leave the variable undefined in the source, and use **-D** to specify the value on the command line; for example:

```
asc14 prog -Dframerate=3
```

This option is identical to the **#define** option in the **ASC14** category in the IAR Embedded Workbench.

---

-E *-Enumber*

This option specifies the maximum number of errors that the assembler report will report.

By default the maximum number is 100. The -E option allows you to decrease or increase this number to see more or fewer errors in a single assembly.

This option is identical to the **Max number of errors** option in the **ASC14** category in the IAR Embedded Workbench.

---

-f *-f extend.xcl*

This option extends the command line with text read from the file named `extend.xcl`. Notice that there must be a space between the option itself and the filename.

The -f option is particularly useful where there is a large number of options which are more conveniently placed in a file than on the command line itself.

**Example**

To run the assembler with further options taken from the file `extend.xcl`, use:

```
asc14 prog -f extend.xcl
```

---

-G *-G*

This option causes the assembler to read the source from the standard input stream, rather than from a specified source file.

When -G is used, no source filename may be specified.

---

-I *-Iprefix*

Use this option to specify paths to be used by the preprocessor by adding the `#include` file search prefix *prefix*.

By default the assembler searches for `#include` files only in the current working directory and in the paths specified in the `ASC14_INC` environment variable. The -I option allows you to give the assembler the names of directories where it will also search if it fails to find the file in the current working directory.

**Example**

Using the options:

```
-Ic:\global\ -Ic:\thisproj\headers\
```

and then writing:

```
#include "asmlib.hdr"
```

in the source, will make the assembler search first in the current directory, then in the directory `c:\global\`, and finally in the directory `c:\thisproj\headers\` provided that the `ASC14_INC` environment variable is set.

This option is related to the **#include** option in the **ASC14** category in the IAR Embedded Workbench.

```
-i -i
```

Includes `#include` files in the list file.

By default the assembler does not list `#include` file lines since these often come from standard files and would waste space in the list file. The `-i` option allows you to list these file lines.

This option is related to the **#include** option in the **ASC14** category in the IAR Embedded Workbench.

```
-L -L[prefix]
```

By default the assembler does not generate a list file. Use this option to make the assembler generate one and send it to file `[prefix] sourcename.lst`.

To simply generate a listing, use the `-L` option without a prefix. The listing is sent to the file with the same name as the source, but the extension will be `lst`.

The `-L` option lets you specify a prefix, for example to direct the list file to a subdirectory. Notice that you must not include a space before the prefix.

`-L` may not be used at the same time as `-l`.

**Example**

To send the list file to `list\prog.lst` rather than the default `prog.lst`:

```
asc14 prog -Llist\
```

This option is related to the **List** options in the **ASC14** category in the IAR Embedded Workbench.

---

`-l filename`

Use this option to make the assembler generate a listing and send it to the file *filename*. If no extension is specified, `lst` is used. Notice that you must include a space before the filename.

By default the assembler does not generate a list file. The `-l` option generates a listing, and directs it to a specific file. To generate a list file with the default filename, use the `-L` option instead.

This option is related to the **List** options in the **ASC14** category in the IAR Embedded Workbench.

---

`-M Mab`

This option sets the characters to be used as left and right quotes of each macro argument to *a* and *b* respectively.

By default the characters are `<` and `>`. The `-M` option allows you to change the quote characters to suit an alternative convention or simply to allow a macro argument to contain `<` or `>` themselves.

### Example

For example, using the option:

```
-M[]
```

in the source you would write, for example:

```
print [>]
```

to call a macro `print` with `>` as the argument.

**Note:** Depending on your host environment, it may be necessary to use quote marks with the macro quote characters, for example:

```
asc14 filename -M'<>'
```

This option is identical to the **Macro quote chars** option in the **ASC14** category in the IAR Embedded Workbench.

---

`-N -N`

Use this option to omit the header section that is printed by default in the beginning of the list file.

This option is useful in conjunction with the list file options `-L` or `-l`; see page 13 for additional information.

This option is related to the **List file** option in the **ASC14** category in the IAR Embedded Workbench.

---

`-O -Oprefix`

Use this option to set the prefix to be used on the name of the object file. Notice that you cannot include a space before the prefix.

By default the prefix is null, so the object filename corresponds to the source filename (unless `-o` is used). The `-O` option lets you specify a prefix, for example to direct the object file to a subdirectory.

Notice that `-O` may not be used at the same time as `-o`.

#### **Example**

To send the object code to the file `obj\prog.r45` rather than to the default file `prog.r45`:

```
asc14 prog -Oobj\
```

This option is related to the **Output directories** option in the **General** category in the IAR Embedded Workbench.

---

`-o -o filename`

This option sets the filename to be used for the object file. Notice that you must include a space before the filename. If no extension is specified, `r45` is used.

The option `-o` may not be used at the same time as the option `-O`.

#### **Example**

For example, the following command puts the object code to the file `obj.r45` instead of the default `prog.r45`:

```
asc14 prog -o obj
```

Notice that you must include a space between the option itself and the filename.

This option is related to the filename and directory that you specify when creating a new source file or project in the IAR Embedded Workbench.

---

`-p` `-p` *lines*

The `-p` option sets the number of lines per page to *lines*, which must be in the range 10 to 150.

This option is used in conjunction with the list options `-L` or `-l`; see page 13 for additional information.

This option is identical to the **Lines/page** option in the **ASC14** category in the IAR Embedded Workbench.

---

`-r` `-r`{*e|n*}

The `-r` option makes the assembler generate debug information that allows a symbolic debugger such as C-SPY to be used on the program.

By default the assembler does not generate debug information, to reduce the size and link time of the object file. You must use the `-r` option if you want to use a debugger with the program.

The following table shows the available parameters:

Command line option	Description
<code>-re</code>	Includes the full source file into the object file
<code>-rn</code>	Generates an object file without source information; symbol information will be available.

Table 9: Generating debug information (`-r`)

This option is identical to the **Generate debug information** option in the **ASC14** category in the IAR Embedded Workbench.

---

`-S` `-S`

The `-S` option causes the assembler to operate without sending any messages to the standard output stream.

By default the assembler sends various insignificant messages via the standard output stream. Use the `-S` option to prevent this.

The assembler sends error and warning messages to the error output stream, so they are displayed regardless of this setting.

---

`-s -s{+|-}`

Use the `-s` option to control whether the assembler is sensitive to the case of user symbols:

Command line option	Description
<code>-s+</code>	Case sensitive user symbols
<code>-s-</code>	Case insensitive user symbols

*Table 10: Controlling case sensitivity in user symbols (-s)*

By default case sensitivity is on. This means that, for example, `LABEL` and `label` refer to different symbols. Use `-s-` to turn case sensitivity off, in which case `LABEL` and `label` will refer to the same symbol.

This option is identical to the **Case sensitive user symbols** option in the **ASC14** category in the IAR Embedded Workbench.

---

`-t -tn`

By default the assembler sets 8 character positions per tab stop. The `-t` option allows you to specify a tab spacing to `n`, which must be in the range 2 to 9.

This option is useful in conjunction with the list options `-L` or `-l`; see page 13 for additional information.

This option is identical to the **Tab spacing** option in the **ASC14** category in the IAR Embedded Workbench.

---

`-U -Usymb`

Use the `-U` option to undefine the predefined symbol `symb`.

By default the assembler provides certain predefined symbols; see *Predefined symbols*, page 4. The `-U` option allows you to undefine such a predefined symbol to make its name available for your own use through a subsequent `-D` option or source definition.

### Example

To use the name of the predefined symbol `__TIME__` for your own purposes, you could undefine it with:

```
asc14 prog -U __TIME__
```

This option is identical to the **#undef** option in the **ASC14** category in the IAR Embedded Workbench.

---

`-v -vSC14xxx`

Use the `-v` option to specify the processor configuration:

Option	Derivative
<code>-vSC14428</code> (default)	SC14428, SC14428-DSP

Table 11: Specifying the processor configuration (`-v`)

The `-v` option is identical to the **Processor configuration** option in the **General** category in the IAR Embedded Workbench.

---

`-w -w[string] [s]`

By default the assembler displays a warning message when it detects an element of the source which is legal in a syntactical sense, but may contain a programming error; see *Assembler diagnostics*, page 71, for details.

Use this option to disable warnings. The `-w` option without a range disables all warnings. The `-w` option with a range performs the following:

Command line option	Description
<code>-w+</code>	Enables all warnings.
<code>-w-</code>	Disables all warnings.
<code>-w+n</code>	Enables just warning <i>n</i> .
<code>-w-n</code>	Disables just warning <i>n</i> .
<code>-w+m-n</code>	Enables warnings <i>m</i> to <i>n</i> .
<code>-w-m-n</code>	Disables warnings <i>m</i> to <i>n</i> .

Table 12: Disabling assembler warnings (`-w`)

Only one `-w` option may be used on the command line.

By default the assembler generates exit code 0 for warnings. Use the `-ws` option to generate exit code 1 if a warning message is produced.

### Example

To disable just warning 0 (unreferenced label), use the following command:

```
asc14 prog -w-0
```

To disable warnings 0 to 8, use the following command:

```
asc14 prog -w-0-8
```

This option is identical to the **Warnings** option in the **ASC14** category in the IAR Embedded Workbench.

---

**-x** **-x [DI2]**

Use this option to make the assembler include a cross-reference table at the end of the list file.

This option is useful in conjunction with the list options `-L` or `-l`; see page 13 for additional information.

The following parameters are available:

Command line option	Description
<code>-xD</code>	<code>#defines</code>
<code>-xI</code>	Internal symbols
<code>-x2</code>	Dual line spacing

*Table 13: Including cross-references in assembler list file (-x)*

This option is identical to the **Include cross-reference** option in the **ASC14** category in the IAR Embedded Workbench.

# Assembler operators

This chapter first describes the precedence of the assembler operators, and then summarizes the operators, classified according to their precedence. Finally, this chapter provides reference information about each operator, presented in alphabetical order.

---

## Precedence of operators

Each operator has a precedence number assigned to it that determines the order in which the operator and its operands are evaluated. The precedence numbers range from 1 (the highest precedence, i.e. first evaluated) to 7 (the lowest precedence, i.e. last evaluated).

The following rules determine how expressions are evaluated:

- The highest precedence operators are evaluated first, then the second highest precedence operators, and so on until the lowest precedence operators are evaluated.
- Operators of equal precedence are evaluated from left to right in the expression.
- Parentheses ( and ) can be used for grouping operators and operands and for controlling the order in which the expressions are evaluated. For example, the following expression evaluates to 1:

$7 / (1 + (2 * 3))$

---

## Summary of assembler operators

The following tables give a summary of the operators, in order of priority. Synonyms, where available, are shown in brackets after the operator name.

### UNARY OPERATORS – I

+	Unary plus.
-	Unary minus.
!	Logical NOT.
BINNOT (~)	Bitwise NOT.
LOW	Low byte.
HIGH	High byte.
BYTE2	Second byte.

BYTE3	Third byte.
BYTE4	Fourth byte
DATE	Current time/date.
SFB	Segment begin.
SFE	Segment end.
SIZEOF	Segment size.

### **MULTIPLICATIVE ARITHMETIC OPERATORS – 3**

*	Multiplication.
/	Division.
%	Modulo.

### **SHIFT OPERATORS – 3**

SHR [ >> ]	Logical shift right.
SHL [ << ]	Logical shift left.

### **ADDITIVE ARITHMETIC OPERATORS – 4**

+	Addition.
-	Subtraction.

### **AND OPERATORS – 5**

AND [ && ]	Logical AND.
BINAND [ & ]	Bitwise AND.

### **OR OPERATORS – 6**

OR [     ]	Logical OR.
BINOR [   ]	Bitwise OR.
XOR	Logical exclusive OR.
BINXOR [ ^ ]	Bitwise exclusive OR.

**COMPARISON OPERATORS – 7**

EQ [=] , [==]	Equal.
NE [<>] , [!=]	Not equal.
GT [>]	Greater than.
LT [<]	Less than.
UGT	Unsigned greater than.
ULT	Unsigned less than.
GE [>=]	Greater than or equal.
LE [<=]	Less than or equal.

---

**Description of operators**

The following sections give detailed descriptions of each assembler operator. See *Assembler expressions*, page 2, for related information.

---

**\* Multiplication (3).**

\* produces the product of its two operands. The operands are taken as signed 32-bit integers and the result is also a signed 32-bit integer.

**Examples**

2\*2 → 4  
-2\*2 → -4

---

**+ Unary plus (1).**

Unary plus operator.

**Examples**

+3 → 3  
3\*+2 → 6

---

**+ Addition (4).**

The + addition operator produces the sum of the two operands which surround it. The operands are taken as signed 32-bit integers and the result is also a signed 32-bit integer.

**Examples**

$92+19 \rightarrow 111$   
 $-2+2 \rightarrow 0$   
 $-2+-2 \rightarrow -4$

---

- Unary minus (1).

The unary minus operator performs arithmetic negation on its operand.

The operand is interpreted as a 32-bit signed integer and the result of the operator is the two's complement negation of that integer.

---

- Subtraction (4).

The subtraction operator produces the difference when the right operand is taken away from the left operand. The operands are taken as signed 32-bit integers and the result is also signed 32-bit integer.

**Examples**

$92-19 \rightarrow 73$   
 $-2-2 \rightarrow -4$   
 $-2--2 \rightarrow 0$

---

/ Division (3).

/ produces the integer quotient of the left operand divided by the right operator. The operands are taken as signed 32-bit integers and the result is also a signed 32-bit integer.

**Examples**

$9/2 \rightarrow 4$   
 $-12/3 \rightarrow -4$   
 $9/2*6 \rightarrow 24$

---

AND [ && ] Logical AND (5).

Use AND to perform logical AND between its two integer operands. If both operands are non-zero the result is 1; otherwise it is zero.

**Examples**

$B'1010 \ \&\& \ B'0011 \rightarrow 1$

**Examples**

BYTE2 0x12345678 → 0x56

---

BYTE3 Third byte (1).

BYTE3 takes a single operand, which is interpreted as an unsigned 32-bit integer value. The result is the middle-high byte (bits 23 to 16) of the operand.

**Examples**

BYTE3 0x12345678 → 0x34

---

BYTE4 Fourth byte (1).

BYTE4 takes a single operand, which is interpreted as an unsigned 32-bit integer value. The result is the middle-high byte (bits 23 to 16) of the operand.

**Examples**

BYTE4 0x12345678 → 0x12

---

DATE Current time/date (1).

Use the DATE operator to specify when the current assembly began.

The DATE operator takes an absolute argument (expression) and returns:

DATE 1 Current second (0–59).

DATE 2 Current minute (0–59).

DATE 3 Current hour (0–23).

DATE 4 Current day (1–31).

DATE 5 Current month (1–12).

DATE 6 Current year MOD 100 (1998 →98, 2000 →00, 2002 →02).

**Examples**

To assemble the date of assembly:

today: DC8 DATE 5, DATE 4, DATE 3

---

EQ [=], [==] Equal (7).

EQ evaluates to 1 (true) if its two operands are identical in value, or to 0 (false) if its two operands are not identical in value.

**Examples**

```
1 = 2 → 0
2 == 2 → 1
'ABC' = 'ABCD' → 0
```

---

GE [>=] Greater than or equal (7).

GE evaluates to 1 (true) if the left operand is equal to or has a higher numeric value than the right operand.

**Examples**

```
1 >= 2 → 0
2 >= 1 → 1
1 >= 1 → 1
```

---

GT [>] Greater than (7).

GT evaluates to 1 (true) if the left operand has a higher numeric value than the right operand.

**Examples**

```
-1 > 1 → 0
2 > 1 → 1
1 > 1 → 0
```

---

HIGH High byte (1).

HIGH takes a single operand to its right which is interpreted as an unsigned, 16-bit integer value. The result is the unsigned 8-bit integer value of the higher order byte of the operand.

**Examples**

```
HIGH 0xABCD → 0xAB
```

---

LE [`<=`] Less than or equal (7)

LE evaluates to 1 (true) if the left operand has a lower or equal numeric value to the right operand.

**Examples**

1 <= 2 → 1  
2 <= 1 → 0  
1 <= 1 → 1

---

LOW Low byte (1).

LOW takes a single operand, which is interpreted as an unsigned, 32-bit integer value. The result is the unsigned, 8-bit integer value of the lower order byte of the operand.

**Examples**

LOW 0xABCD → 0xCD

---

LT [`<`] Less than (7).

LT evaluates to 1 (true) if the left operand has a lower numeric value than the right operand.

**Examples**

-1 < 2 → 1  
2 < 1 → 0  
2 < 2 → 0

---

MOD [`%`] Modulo (3).

MOD produces the remainder from the integer division of the left operand by the right operand. The operands are taken as signed 32-bit integers and the result is also a signed 32-bit integer.

$X \% Y$  is equivalent to  $X - Y * (X / Y)$  using integer division.

**Examples**

2 % 2 → 0  
12 % 7 → 5  
3 % 2 → 1

---

NE [ $<>$ ], [ $!=$ ] Not equal (7).

NE evaluates to 0 (false) if its two operands are identical in value or to 1 (true) if its two operands are not identical in value.

**Examples**

```
1 <> 2 → 1
2 <> 2 → 0
'A' <> 'B' → 1
```

---

NOT [!] Logical NOT (1).

Use NOT to negate a logical argument.

**Examples**

```
! B'0101 → 0
! B'0000 → 1
```

---

OR [||] Logical OR (6).

Use OR to perform a logical OR between two integer operands.

**Examples**

```
B'1010 || B'0000 → 1
B'0000 || B'0000 → 0
```

---

SFB Segment begin (1).

**Syntax**

`SFB(segment [{+ | -} offset])`

**Parameters**

*segment*      The name of a relocatable segment, which must be defined before SFB is used.

*offset*        An optional offset from the start address. The parentheses are optional if *offset* is omitted.

## Description

SFB accepts a single operand to its right. The operand must be the name of a relocatable segment.

The operator evaluates to the absolute address of the first byte of that segment. This evaluation takes place at linking time.

## Examples

```

                NAME  demo
                RSEG  CODE
start: DC16    SFB(CODE)

```

Even if the above code is linked with many other modules, `start` will still be set to the address of the first byte of the segment.

---

SFE Segment end (1).

## Syntax

SFE (*segment* [{+ | -} *offset*])

## Parameters

*segment*            The name of a relocatable segment, which must be defined before SFE is used.

*offset*             An optional offset from the start address. The parentheses are optional if `offset` is omitted.

## Description

SFE accepts a single operand to its right. The operand must be the name of a relocatable segment. The operator evaluates to the segment start address plus the segment size. This evaluation takes place at linking time.

## Examples

```

                NAME  demo
                RSEG  CODE
end:   DC16    SFE(CODE)

```

Even if the above code is linked with many other modules, `end` will still be set to the address of the last byte of the segment.

---

SHL [ $\ll$ ] Logical shift left (3).

Use SHL to shift the left operand, which is always treated as unsigned, to the left. The number of bits to shift is specified by the right operand, interpreted as an integer value between 0 and 32.

#### Examples

```
B'00011100 << 3 → B'11100000
B'0000011111111111 << 5 → B'1111111111110000
14 << 1 → 28
```

---

SHR [ $\gg$ ] Logical shift right (3).

Use SHR to shift the left operand, which is always treated as unsigned, to the right. The number of bits to shift is specified by the right operand, interpreted as an integer value between 0 and 32.

#### Examples

```
B'01110000 >> 3 → B'00001110
B'1111111111111111 >> 20 → 0
14 >> 1 → 7
```

---

SIZEOF Segment size (1).

### Syntax

SIZEOF *segment*

### Parameters

<i>segment</i>	The name of a relocatable segment, which must be defined before SIZEOF is used.
----------------	---

### Description

SIZEOF generates SFE-SFB for its argument, which should be the name of a relocatable segment; i.e. it calculates the size in bytes of a segment. This is done when modules are linked together.

#### Examples

```
NAME    demo
RSEG    CODE
```

```
size: DC16    SIZEOF CODE
```

sets `size` to the size of segment `CODE`.

---

UGT Unsigned greater than (7).

UGT evaluates to 1 (true) if the left operand has a larger value than the right operand. The operation treats its operands as unsigned values.

**Examples**

```
2 UGT 1 → 1
-1 UGT 1 → 1
```

---

ULT Unsigned less than (7).

ULT evaluates to 1 (true) if the left operand has a smaller value than the right operand. The operation treats its operands as unsigned values.

**Examples**

```
1 ULT 2 → 1
-1 ULT 2 → 0
```

---

XOR Logical exclusive OR (6).

Use XOR to perform logical XOR on its two operands.

**Examples**

```
B'0101 XOR B'1010 → 0
B'0101 XOR B'0000 → 1
```

# Assembler directives

This chapter gives an alphabetical summary of the assembler directives. It then describes the syntax conventions and provides detailed reference information for each category of directives.

---

## Summary of directives

The following table gives a summary of all the assembler directives.

Directive	Description	Section
<code>\$</code>	Includes a file.	Assembler control
<code>#define</code>	Assigns a value to a label.	C-style preprocessor
<code>#elif</code>	Introduces a new condition in a <code>#if...#endif</code> block.	C-style preprocessor
<code>#else</code>	Assembles instructions if a condition is false.	C-style preprocessor
<code>#endif</code>	Ends a <code>#if</code> , <code>#ifdef</code> , or <code>#ifndef</code> block.	C-style preprocessor
<code>#error</code>	Generates an error.	C-style preprocessor
<code>#if</code>	Assembles instructions if a condition is true.	C-style preprocessor
<code>#ifdef</code>	Assembles instructions if a symbol is defined.	C-style preprocessor
<code>#ifndef</code>	Assembles instructions if a symbol is undefined.	C-style preprocessor
<code>#include</code>	Includes a file.	C-style preprocessor
<code>#message</code>	Generates a message on standard output.	C-style preprocessor
<code>#undef</code>	Undefines a label.	C-style preprocessor
<code>/*comment*/</code>	C-style comment delimiter.	Assembler control
<code>//</code>	C++ style comment delimiter.	Assembler control
<code>=</code>	Assigns a permanent value local to a module.	Value assignment
<code>ALIAS</code>	Assigns a permanent value local to a module.	Value assignment
<code>ALIGN</code>	Aligns the location counter by inserting zero-filled bytes.	Segment control
<code>ASEG</code>	Begins an absolute segment.	Segment control
<code>ASSIGN</code>	Assigns a temporary value.	Value assignment
<code>CASEOFF</code>	Disables case sensitivity.	Assembler control
<code>CASEON</code>	Enables case sensitivity.	Assembler control

*Table 14: Assembler directives summary*

<b>Directive</b>	<b>Description</b>	<b>Section</b>
COL	Sets the number of columns per page.	Listing control
COMMON	Begins a common segment.	Segment control
DB	Generates 8-bit byte constants, including strings.	Data definition or allocation
DC8	Generates 8-bit byte constants, including strings.	Data definition or allocation
DC16	Generates 16-bit word constants, including strings.	Data definition or allocation
DEFINE	Defines a file-wide value.	Value assignment
DQ15	Generates 16-bit fixed-point values.	Data definition or allocation
DS	Allocates space for 8-bit bytes.	Data definition or allocation
DS8	Allocates space for 8-bit bytes.	Data definition or allocation
DS16	Allocates space for 16-bit words.	Data definition or allocation
DW	Generates 16-bit word constants, including strings.	Data definition or allocation
ELSE	Assembles instructions if a condition is false.	Conditional assembly
ELSEIF	Specifies a new condition in an IF...ENDIF block.	Conditional assembly
END	Terminates the assembly of the last module in a file.	Module control
ENDIF	Ends an IF block.	Conditional assembly
ENDM	Ends a macro definition.	Macro processing
ENDMOD	Terminates the assembly of the current module.	Module control
EQU	Assigns a permanent value local to a module.	Value assignment
EVEN	Aligns the program counter to an even address.	Segment control
EXITM	Exits prematurely from a macro.	Macro processing
EXPORT	Exports symbols to other modules.	Symbol control
EXTERN	Imports an external symbol.	Symbol control
IF	Assembles instructions if a condition is true.	Conditional assembly
IMPORT	Imports an external symbol.	Symbol control

Table 14: Assembler directives summary (Continued)

<b>Directive</b>	<b>Description</b>	<b>Section</b>
LIBRARY	Begins a library module.	Module control
LIMIT	Checks a value against limits.	Value assignment
LOCAL	Creates symbols local to a macro.	Macro processing
LSTCND	Controls conditional assembly listing.	Listing control
LSTCOD	Controls multi-line code listing.	Listing control
LSTEXP	Controls the listing of macro generated lines.	Listing control
LSTMAC	Controls the listing of macro definitions.	Listing control
LSTOUT	Controls assembly-listing output.	Listing control
LSTPAG	Controls the formatting of output into pages.	Listing control
LSTREP	Controls the listing of lines generated by repeat directives.	Listing control
LSTXRF	Generates a cross-reference table.	Listing control
MACRO	Defines a macro.	Macro processing
MODULE	Begins a library module.	Module control
NAME	Begins a program module.	Module control
ODD	Aligns the program counter to an odd address.	Segment control
ORG	Sets the location counter.	Segment control
PAGE	Generates a new page.	Listing control
PAGSIZ	Sets the number of lines per page.	Listing control
PROGRAM	Begins a program module.	Module control
PUBLIC	Exports symbols to other modules.	Symbol control
RADIX	Sets the default base.	Assembler control
REPT	Assembles instructions a specified number of times.	Macro processing
REPTC	Repeats and substitutes characters.	Macro processing
RSEG	Begins a relocatable segment.	Segment control
RTMODEL	Declares run-time model attributes.	Module control
SET	Assigns a temporary value.	Value assignment
VAR	Assigns a temporary value.	Value assignment

*Table 14: Assembler directives summary (Continued)*

---

## Syntax conventions

In the syntax definitions the following conventions are used:

Parameters, representing what you would type, are shown in italics. So, for example, in:

```
ORG expr
```

*expr* represents an arbitrary expression.

Optional parameters are shown in square brackets. So, for example, in:

```
END [expr]
```

the *expr* parameter is optional. An ellipsis indicates that the previous item can be repeated an arbitrary number of times. For example:

```
PUBLIC symbol [, symbol] ...
```

indicates that PUBLIC can be followed by one or more symbols, separated by commas.

Alternatives are enclosed in { and } brackets, separated by a vertical bar, for example:

```
LSTOUT{+|-}
```

indicates that the directive must be followed by either + or -.

### LABELS AND COMMENTS

Where a label *must* precede a directive, this is indicated in the syntax, as in:

```
label VAR expr
```

An optional label, which will assume the value and type of the current program location counter (PLC), can precede all directives. For clarity, this is not included in each syntax definition.

In addition, unless explicitly specified, all directives can be followed by a comment, preceded by ; (semicolon).

### PARAMETERS

The following table shows the correct form of the most commonly used types of parameter:

Parameter	What it consists of
<i>expr</i>	An expression; see <i>Assembler expressions</i> , page 2.
<i>label</i>	A symbolic label.
<i>symbol</i>	An assembler symbol.

Table 15: Assembler directive parameters

## Module control directives

Module control directives are used for marking the beginning and end of source program modules, and for assigning names and types to them.

Directive	Description
END	Terminates the assembly of the last module in a file.
ENDMOD	Terminates the assembly of the current module.
LIBRARY	Begins a library module.
MODULE	Begins a library module.
NAME	Begins a program module.
PROGRAM	Begins a program module.
RTMODEL	Declares run-time model attributes.

Table 16: Module control directives

### SYNTAX

```

END [label]
ENDMOD [label]
LIBRARY symbol [(expr)]
MODULE symbol [(expr)]
NAME symbol [(expr)]
PROGRAM symbol [(expr)]
RTMODEL key, value

```

### PARAMETERS

*expr* Optional expression (0–255) used by the IAR compiler to encode programming language, memory model, and processor configuration.

*key* A text string specifying the key.

*label* An expression or label that can be resolved at assembly time. It is output in the object code as a program entry address.

*symbol* Name assigned to module, used by XLINK and XLIB when processing object files.

*value* A text string specifying the value.

## DESCRIPTION

### Beginning a program module

Use `NAME` to begin a program module, and to assign a name for future reference by the IAR XLINK Linker™ and the IAR XLIB Librarian™.

Program modules are unconditionally linked by XLINK, even if other modules do not reference them.

### Beginning a library module

Use `MODULE` to create libraries containing lots of small modules—like run-time systems for high-level languages—where each module often represents a single routine. With the multi-module facility, you can significantly reduce the number of source and object files needed.

Library modules are only copied into the linked code if other modules reference a public symbol in the module.

### Terminating a module

Use `ENDMOD` to define the end of a module.

### Terminating the last module

Use `END` to indicate the end of the source file. Any lines after the `END` directive are ignored.

### Assembling multi-module files

Program entries must be either relocatable or absolute, and will show up in XLINK load maps, as well as in some of the hexadecimal absolute output formats. Program entries must not be defined externally.

The following rules apply when assembling multi-module files:

- At the beginning of a new module all user symbols are deleted, except for those created by `DEFINE`, `#define`, or `MACRO`, the location counters are cleared, and the mode is set to absolute.
- Listing control directives remain in effect throughout the assembly.

**Note:** `END` must always be used in the *last* module, and there must not be any source lines (except for comments and listing control directives) between an `ENDMOD` and a `MODULE` directive.

If the `NAME` or `MODULE` directive is missing, the module will be assigned the name of the source file and the attribute `program`.

## Symbol control directives

These directives control how symbols are shared between modules.

Directive	Description
EXTERN (IMPORT)	Imports an external symbol.
PUBLIC (EXPORT)	Exports symbols to other modules.

Table 17: Symbol control directives

### SYNTAX

```
EXTERN symbol [, symbol] ...
PUBLIC symbol [, symbol] ...
```

### PARAMETERS

*symbol*                      Symbol to be imported or exported.

### DESCRIPTION

#### Exporting symbols to other modules

Use `PUBLIC` to make one or more symbols available to other modules. The symbols declared as `PUBLIC` can only be assigned values by using them as labels. Symbols declared `PUBLIC` can be relocated or absolute, and can also be used in expressions (with the same rules as for other symbols).

The `PUBLIC` directive always exports full 32-bit values, which makes it feasible to use global 32-bit constants also in assemblers for 8-bit and 16-bit processors. With the `LOW`, `HIGH`, `>>`, and `<<` operators, any part of such a constant can be loaded in an 8-bit or 16-bit register or word.

There are no restrictions on the number of `PUBLIC`-declared symbols in a module.

#### Importing symbols

Use `EXTERN` to import an untyped external symbol.

### EXAMPLES

The following example defines two subroutines to set the power pins high or low. The `pow_high` and `pow_low` subroutines are defined as `PUBLIC` so that they can be called from other modules.

```
MODULE pow_high
PUBLIC pow_high
```

```

                                RSEG    CODE

pow_high  P_EN                // make sure that power pins are enabled
          P_LDH    0xFF // set all pins high
          RTN
          ENDMOD                // end of module

                                MODULE  pow_low
                                PUBLIC  pow_low
                                RSEG    CODE

pow_low   P_EN                // make sure that power pins are enabled
          P_LDH    0x00 // set all pins low
          RTN
          ENDMOD                // end of module

                                END

```

---

## Segment control directives

The segment directives control how code and data are generated.

Directive	Description
ALIGN	Aligns the location counter by inserting zero-filled bytes.
ASEG	Begins an absolute segment.
COMMON	Begins a common segment.
EVEN	Aligns the program counter to an even address.
ODD	Aligns the program counter to an odd address.
ORG	Sets the location counter.
RSEG	Begins a relocatable segment.

Table 18: Segment control directives

### SYNTAX

```

ALIGN align [, value]
ASEG [start [(align)]]
COMMON segment [:type] [(align)]
EVEN [value]
ODD [value]
ORG expr
RSEG segment [:type] [flag] [(align)]
RSEG segment [:type], address

```

## PARAMETERS

<i>address</i>	Address where this segment part will be placed.
<i>align</i>	Exponent of the value to which the address should be aligned, in the range 0 to 30. For example, <code>align 1</code> results in word alignment 2.
<i>expr</i>	Address to set the location counter to.
<i>flag</i>	<p>NOROOT This segment part may be discarded by the linker even if no symbols in this segment part are referred to. Normally all segment parts except startup code and interrupt vectors should set this flag. The default mode is <code>ROOT</code> which indicates that the segment part must not be discarded.</p> <p>REORDER Allows the linker to reorder segment parts. For a given segment, all segment parts must specify the same state for this flag. The default mode is <code>NOREORDER</code> which indicates that the segment parts must remain in order.</p> <p>SORT The linker will sort the segment parts in decreasing alignment order. For a given segment, all segment parts must specify the same state for this flag. The default mode is <code>NOSORT</code> which indicates that the segment parts will not be sorted.</p>
<i>segment</i>	The name of the segment.
<i>start</i>	A start address that has the same effect as using an <code>ORG</code> directive at the beginning of the absolute segment.
<i>type</i>	The memory type; one of <code>UNTYPED</code> (the default), <code>CODE</code> , or <code>DATA</code> .
<i>value</i>	Byte value used for padding, default is zero.

## DESCRIPTION

### Beginning an absolute segment

Use `ASEG` to set the absolute mode of assembly, which is the default at the beginning of a module.

If the parameter is omitted, the start address of the first segment is 0, and subsequent segments continue after the last address of the previous segment.

**Note:** The use of `ASEG` is not recommended in the SC14 IAR Assembler. Instead, use `RSEG` to specify the `DIP_CODE` segment.

### Beginning a relocatable segment

Use `RSEG` to set the current mode of the assembly to relocatable assembly mode. The assembler maintains separate location counters (initially set to zero) for all segments, which makes it possible to switch segments and mode anytime without the need to save the current segment location counter.

Up to 65536 unique, relocatable segments may be defined in a single module.

### Beginning a common segment

Use `COMMON` to place data in memory at the same location as `COMMON` segments from other modules that have the same name. In other words, all `COMMON` segments of the same name will start at the same location in memory and overlay each other.

Obviously, the `COMMON` segment type should not be used for overlaid executable code. A typical application would be when you want a number of different routines to share a reusable, common area of memory for data.

It can be practical to have the interrupt vector table in a `COMMON` segment, thereby allowing access from several routines.

The final size of the `COMMON` segment is determined by the size of largest occurrence of this segment. The location in memory is determined by the `XLINK -z` command; see the *IAR XLINK Linker™ and IAR XLIB Librarian™ Reference Guide*.

Use the `align` parameter in any of the above directives to align the segment start address.

### Setting the program location counter (PLC)

Use `ORG` to set the program location counter of the current segment to the value of an expression. The optional label will assume the value and type of the new location counter.

The result of the expression must be of the same type as the current segment, i.e. it is not valid to use `ORG 10` during `RSEG`, since the expression is absolute; use `ORG $+10` instead. The expression must not contain any forward or external references.

All program location counters are set to zero at the beginning of an assembler module.

### Aligning a segment

Use `ALIGN` to align the program location counter to a specified address boundary. The expression gives the power of two to which the program counter should be aligned.

The alignment is made relative to the segment start; normally this means that the segment alignment must be at least as large as that of the alignment directive to give the desired result.

`ALIGN` aligns by inserting zero/filled bytes. The `EVEN` directive aligns the program counter to an even address (which is equivalent to `ALIGN 1`) and the `ODD` directive aligns the program counter to an odd address.

## EXAMPLES

### Beginning a common segment

The following example defines two common segments containing variables:

```

                NAME    common1
                COMMON  data
count          DS16   2
                endmod

                NAME    common2
                COMMON  data
up             DS8    1
                ORG     $+2
down          DS8    1

                END

```

Because the common segments have the same name, `data`, the variables `up` and `down` refer to the same locations in memory as the first and last bytes of the 4-byte variable `count`.

### Aligning a segment

This example starts a relocatable segment, moves to an odd address, and adds some data. It then aligns to a 16-byte boundary before creating a 64-byte table.

```

                NAME    ALIGN_EX
                RSEG    CODE
                ORG     $+1
                EVEN

                DC8     1,2

                ENDMOD
                END

```

It generates the following code:

```

1      0000
2      0000      NAME      ALIGN_EX
3      0000      RSEG      CODE
4      0001      ORG       $+1
5      0001 00      EVEN
6      0002
7      0002 0201      DC8      1, 2
8      0004
9      0004      ENDMOD

```

---

## Value assignment directives

These directives are used for assigning values to symbols.

Directive	Description
=	Assigns a permanent value local to a module.
ALIAS	Assigns a permanent value local to a module.
ASSIGN	Assigns a temporary value.
DEFINE	Defines a file-wide value.
EQU	Assigns a permanent value local to a module.
LIMIT	Checks a value against limits.
SET	Assigns a temporary value.

*Table 19: Value assignment directives*

### SYNTAX

```

label = expr
label ALIAS expr
label ASSIGN expr
label DEFINE expr
label EQU expr
LIMIT expr, min, max, message
label SET expr

```

### PARAMETERS

<i>expr</i>	Value assigned to symbol or value to be tested.
<i>label</i>	Symbol to be defined.
<i>message</i>	A text message that will be printed when <i>expr</i> is out of range.

*min*, *max*            The minimum and maximum values allowed for *expr*.

## DESCRIPTION

### Defining a temporary value

Use either of `ASSIGN` and `SET` to define a symbol that may be redefined, such as for use with macro variables. Symbols defined with `SET` cannot be declared `PUBLIC`.

### Defining a permanent local value

Use `EQU` or `=` to assign a value to a symbol.

Use `EQU` to create a local symbol that denotes a number or offset.

The symbol is only valid in the module in which it was defined, but can be made available to other modules with a `PUBLIC` directive.

Use `EXTERN` to import symbols from other modules.

### Defining a permanent global value

Use `DEFINE` to define symbols that should be known to all modules in the source file.

A symbol which has been given a value with `DEFINE` can be made available to modules in other files with the `PUBLIC` directive.

Symbols defined with `DEFINE` cannot be redefined within the same file.

### Checking symbol values

Use `LIMIT` to check that expressions lie within a specified range. If the expression is assigned a value outside the range, an error message will appear.

The check will occur as soon as the expression is resolved, which will be during linking if the expression contains external references. The *min* and *max* expressions cannot involve references to forward or external labels, that is, they must be resolved when encountered.

## EXAMPLES

### Redefining a symbol

The following example uses `SET` to redefine the symbol `cons` in a loop to generate a table of the first 4 powers of 3:

```
cons    SET    1
```

```

rep    MACRO    times
      DB      cons
cons   SET      cons*3
      IF      times>1
      rep    times-1
      ENDIF
      ENDM

      rep    4

      END

```

It generates the following code:

```

1      0000
2      0001      cons   SET    1
3      0000
11     0000
12     0000      rep    4
12.1   0000 01      DB     cons
12.2   0003      cons   SET    cons*3
12.3   0001      IF     4>1
12     0001      rep    4-1
12.1   0001 03      DB     cons
12.2   0009      cons   SET    cons*3
12.3   0002      IF     4-1>1
12     0002      rep    4-1-1
12.1   0002 09      DB     cons
12.2   001B      cons   SET    cons*3
12.3   0003      IF     4-1-1>1
12     0003      rep    4-1-1-1
12.1   0003 1B      DB     cons
12.2   0051      cons   SET    cons*3
12.3   0004      IF     4-1-1-1>1
12.4   0004      rep    4-1-1-1-1
12.5   0004      ENDIF
12.6   0004      ENDM
12.7   0004      ENDIF
12.8   0004      ENDM
12.9   0004      ENDIF
12.10  0004      ENDM
12.11  0004      ENDIF
12.12  0004      ENDM
13     0004
14     0004      END

```

## Using local and global symbols

In the following example the symbol `x` defined in module `Local_1` is local to that module; a distinct symbol of the same name is defined in module `Local_2`. The `DEFINE` directive is used for declaring `y` for use anywhere in the file:

```

        NAME      Local_1
        RSEG      CODE

x      EQU       1
y      DEFINE    2

        WT       x      ; WT 1
        WT       y      ; WT 2

        ENDMOD

        NAME      Local_2
        RSEG      CODE

x      EQU       4

        WT       x      ; WT 4
        WT       y      ; WT 2

        ENDMOD
        END

```

The symbol `y` defined in module `Local_1` is also available to module `Local_2`.

It generates the following code:

```

1      0000      NAME      Local_1
2      0000      RSEG      CODE
3      0000
4      0001      x      EQU       1
5      0002      y      DEFINE    2
6      0000
7      1 0000 0109      WT       x      ; WT 1
8      1 0002 0209      WT       y      ; WT 2
9      0004
10     0004      ENDMOD

11     0000
12     0000
13     0000      NAME      Local_2
14     0000      RSEG      CODE
15     0000

```

```

16          0004          x  EQU      4
17          0000
18      1 0000 0409          WT      x  ; WT  4
19      1 0002 0209          WT      y  ; WT  2
20          0004
21          0004          ENDMOD

```

### Using the LIMIT directive

The following example sets the value of a variable called `speed` and then checks it, at assembly time, to see if it is in the range 10 to 30. This might be useful if `speed` is often changed at compile time, but values outside a defined range would cause undesirable behavior.

```

speed      VAR          23
LIMIT     speed,10,30,...speed out of range...

```

---

## Conditional assembly directives

These directives provide logical control over the selective assembly of source code.

Directive	Description
IF	Assembles instructions if a condition is true.
ELSE	Assembles instructions if a condition is false.
ELSEIF	Specifies a new condition in an IF...ENDIF block.
ENDIF	Ends an IF block.

Table 20: Conditional assembly directives

### SYNTAX

```

IF condition
ELSE
ELSEIF condition
ENDIF

```

### PARAMETERS

*condition* One of the following:

An absolute expression

The expression must not contain forward or external references, and any non-zero value is considered as true.

<code>string1=string2</code>	The condition is true if <i>string1</i> and <i>string2</i> have the same length and contents.
<code>string1&lt;&gt;string2</code>	The condition is true if <i>string1</i> and <i>string2</i> have different length or contents.

## DESCRIPTION

Use the `IF`, `ELSE`, and `ENDIF` directives to control the assembly process at assembly time. If the condition following the `IF` directive is not true, the subsequent instructions will not generate any code (i.e. it will not be assembled or syntax checked) until an `ELSE` or `ENDIF` directive is found.

Use `ELSEIF` to introduce a new condition after an `IF` directive. Conditional assembler directives may be used anywhere in an assembly, but have their greatest use in conjunction with macro processing.

All assembler directives (except `END`) as well as the inclusion of files may be disabled by the conditional directives. Each `IF` directive must be terminated by an `ENDIF` directive. The `ELSE` directive is optional; it can only be used inside an `IF . . . ENDIF` block. `IF . . . ENDIF` and `IF . . . ELSE . . . ENDIF` blocks may be nested to any level.

## EXAMPLES

The following macro shows the usage both of macro quotes and of the `IF`, `ELSE`, and `ENDIF` directives. The first line in the macro checks the number of arguments passed to the macro.

```
MACRO    mac
        IF _args == 2
            DW    \0 + \1
        ELSE
            DW    \0
        ENDIF
        ENDMAC

ASEG

mac    2,2    ; two arguments passed to the macro
mac    <2,2> ; passed as one argument

END
```

It produces the following code:

```

15      0000      ASEG
16      0000
17      0000      mac   2,2      ; two arguments passed to the
                                ; macro

17.1    0000      IF   _args == 2
17.2    0000 0400      DW   2 + 2
17.3    0002      ELSE
17.4    0002      DW   2
17.5    0002      ENDIF
17.6    0002      ENDMAC
18      0002      mac   <2,2>      ; passed as one argument
18.1    0002      IF   _args == 2
18.2    0002      DW   2,2 +
18.3    0002      ELSE
18.4    0002 02000200      DW   2,2
18.5    0006      ENDIF
18.6    0006      ENDMAC
19      0006
20      0006      END

```

---

## Macro processing directives

These directives allow user macros to be defined.

Directive	Description
ENDM	Ends a macro definition.
ENDR	Ends a repeat structure.
EXITM	Exits prematurely from a macro.
LOCAL	Creates symbols local to a macro.
MACRO	Defines a macro.
REPT	Assembles instructions a specified number of times.
REPTC	Repeats and substitutes characters.
REPTI	Repeats and substitutes strings.

*Table 21: Macro processing directives*

### SYNTAX

```

ENDM
ENDR
EXITM
LOCAL symbol [, symbol] ...

```

```

name MACRO [argument] ...
REPT expr
REPTC formal, actual
REPTI formal, actual [, actual] ...

```

## PARAMETERS

<i>actual</i>	String to be substituted.
<i>argument</i>	A symbolic argument name.
<i>expr</i>	An expression.
<i>formal</i>	Argument into which each character of <i>actual</i> (REPTC) or each <i>actual</i> (REPTI) is substituted.
<i>name</i>	The name of the macro.
<i>symbol</i>	Symbol to be local to the macro.

## DESCRIPTION

A macro is a user-defined symbol that represents a block of one or more assembler source lines. Once you have defined a macro you can use it in your program like an assembler directive or assembler mnemonic.

When the assembler encounters a macro, it looks up the macro's definition, and inserts the lines that the macro represents as if they were included in the source file at that position.

Macros perform simple text substitution effectively, and you can control what they substitute by supplying parameters to them.

### Defining a macro

You define a macro with the statement:

```

macroname MACRO [arg] [arg] ...

```

Here *macroname* is the name you are going to use for the macro, and *arg* is an argument for values that you want to pass to the macro when it is expanded.

For example, you could define a macro `ERROR` as follows:

```

errmac  MACRO   text
        JMP     abort
        DC8    text, 0
        ENDM

```

This uses a parameter text to set up an error message for a routine abort. You would call the macro with a statement such as:

```
errmac 'Disk not ready'
```

This will be expanded by the assembler to:

```
JMP      abort
DC8      'Disk not ready', 0
```

If you omit a list of one or more arguments, the arguments you supply when calling the macro are called \1 to \9 and \A to \Z.

The previous example could therefore be written as follows:

```
errmac  MACRO
        JMP      abort
        DC8      1, 0
        ENDM
```

Use the EXITM directive to generate a premature exit from a macro.

EXITM is not allowed inside REPT...ENDR, REPTC...ENDR, or REPTI...ENDR blocks.

Use LOCAL to create symbols local to a macro. The LOCAL directive must be used before the symbol is used.

Each time that a macro is expanded, new instances of local symbols are created by the LOCAL directive. Therefore, it is legal to use local symbols in recursive macros.

**Note:** It is illegal to *redefine* a macro.

### Passing special characters

Macro arguments that include commas or white space can be forced to be interpreted as one argument by using the matching quote characters < and > in the macro call.

For example:

```
macro    <A, #42H>
        END
```

You can redefine the macro quote characters with the -M command line option; see -M, page 14.

## Using macro quotes

This macro shows the usage of macro quotes. The first call will generate the code "DW 2+2" while the second call, which uses macro quotes, will generate "DW 2,2".

```

MACRO    mac
        IF _args == 2
            DW    \0 + \1
        ELSE
            DW    \0
        ENDIF
    ENDMAC

    ASEG

    mac    2,2    ; two arguments passed to the macro
    mac    <2,2> ; passed as one argument

    END

```

It will produce the following code:

```

15      0000      ASEG
16      0000
17      0000      mac    2,2    ; two arguments passed
                    ; to the macro
17.1    0000      IF _args == 2
17.2    0000 0400      DW    2 + 2
17.3    0002      ELSE
17.4    0002      DW    2
17.5    0002      ENDIF
17.6    0002      ENDMAC
18      0002      mac    <2,2> ; passed as one argument
18.1    0002      IF _args == 2
18.2    0002      DW    2,2 +
18.3    0002      ELSE
18.4    0002 02000200      DW    2,2
18.5    0006      ENDIF
18.6    0006      ENDMAC
19      0006
20      0006      END

```

## How macros are processed

There are three distinct phases in the macro process:

- 1 The assembler performs scanning and saving of macro definitions. The text between `MACRO` and `ENDM` is saved but not syntax checked. Include-file references *\$file* are recorded and will be included during macro *expansion*.
- 2 A macro call forces the assembler to invoke the macro processor (expander). The macro expander switches (if not already in a macro) the assembler input stream from a source file to the output from the macro expander. The macro expander takes its input from the requested macro definition.  
The macro expander has no knowledge of assembler symbols since it only deals with text substitutions at source level. Before a line from the called macro definition is handed over to the assembler, the expander scans the line for all occurrences of symbolic macro arguments, and replaces them with their expansion arguments.
- 3 The expanded line is then processed as any other assembler source line. The input stream to the assembler will continue to be the output from the macro processor, until all lines of the current macro definition have been read.

## Repeating statements

Use the `REPT . . . ENDR` structure to assemble the same block of instructions a number of times. If *expr* evaluates to 0 nothing will be generated.

Use `REPTC` to assemble a block of instructions once for each character in a string. If the string contains a comma it should be enclosed in quotation marks.

Only double quotes have a special meaning and its only use is to enclose the characters to iterate over. Single quotes have no special meaning and are treated as any ordinary character.

Use `REPTI` to assemble a block of instructions once for each string in a series of strings. Strings containing commas should be enclosed in quotation marks.

## EXAMPLES

This section gives examples of the different ways in which macros can make assembler programming easier.

### Coding in-line for efficiency

In time-critical code it is often desirable to code routines in-line to avoid the overhead of a subroutine call and return. Macros provide a convenient way of doing this.

The following macros sets the power pins:

```
MACRO power_pins_high // no use of incoming argument
    P_EN              // make sure that power pins are enabled
    P_LDH    0xFF    // set all pins high
    ENDMAC           // end of macro
```

```
MACRO power_pins_low // no use of incoming argument
    P_EN              // make sure that power pins are enabled
    P_LDH    0x00    // set all pins low
    ENDMAC           // end of macro
```

The macros would be called with a statement such as:

```
power_pins_high
```

The following program calls the macros from the file `macros.s44`:

```
                RSEG    DIP_CODE
#include "macros.s44"

                WT      0x04
                JMP     init
                power_pins_high
                JMP     mute
                BR      QUIT

mute    A_RCV36
        RTN

init    A_NORM
        RTN

QUIT    WNT      0x01
        END
```

## Using REPTC and REPTI

The following example assembles a series of DBs to store a version string in memory to a subroutine `plot` to plot each character in a string:

```
RSEG    DIP_DATA

REPTC   char, "Version 1.21A"
DB      'char'
ENDR
END
```

This produces the following code:

```

1      0000      RSEG  DIP_DATA
2      0000
3      0000      REPTC  char, "Version 1.21A"
4      0000      DB    'char'
5      0000      ENDR
5.1    0000 56   DB    'V'
5.2    0001 65   DB    'e'
5.3    0002 72   DB    'r'
5.4    0003 73   DB    's'
5.5    0004 69   DB    'i'
5.6    0005 6F   DB    'o'
5.7    0006 6E   DB    'n'
5.8    0007 20   DB    ' '
5.9    0008 31   DB    '1'
5.10   0009 2E   DB    '.'
5.11   000A 32   DB    '2'
5.12   000B 31   DB    '1'
5.13   000C 41   DB    'A'
6      000D      END

```

The following example uses REPTI to define a number of memory locations:

```

RSEG
EXTERN x,y,z

REPTI number, x, y, z
DW    number
ENDR
END

```

This produces the following code:

```

1      0000      RSEG
2      0000      EXTERN x,y,z
3      0000
4      0000      REPTI  number, x, y, z
5      0000      DW    number
6      0000      ENDR
6.1    0000 ....   DW    x
6.2    0002 ....   DW    y
6.3    0004 ....   DW    z
7      0006      END

```

## Listing control directives

These directives provide control over the assembler list file.

Directive	Description
COL	Sets the number of columns per page.
LSTCND	Controls conditional assembly listing.
LSTCOD	Controls multi-line code listing.
LSTEXP	Controls the listing of macro-generated lines.
LSTMAC	Controls the listing of macro definitions.
LSTOUT	Controls assembly-listing output.
LSTPAG	Controls the formatting of output into pages.
LSTREP	Controls the listing of lines generated by repeat directives.
LSTXRF	Generates a cross-reference table.
PAGE	Generates a new page.
PAGSIZ	Sets the number of lines per page.

Table 22: Listing control directives

### SYNTAX

COL *columns*

LSTCND{+ | -}

LSTCOD{+ | -}

LSTEXP{+ | -}

LSTMAC{+ | -}

LSTOUT{+ | -}

LSTPAG{+ | -}

LSTREP{+ | -}

LSTXRF{+ | -}

PAGE

PAGSIZ *lines*

### PARAMETERS

*columns* An absolute expression in the range 80 to 132, default is 80

*lines* An absolute expression in the range 10 to 150, default is 44

## DESCRIPTION

### Turning the listing on or off

Use `LSTOUT-` to disable all list output except error messages. This directive overrides all other listing control directives.

The default is `LSTOUT+`, which lists the output (if a list file was specified).

### Listing conditional code and strings

Use `LSTCND+` to force the assembler to list source code only for the parts of the assembly that are not disabled by previous conditional `IF` statements, `ELSE`, or `END`.

The default setting is `LSTCND-`, which lists all source lines.

Use `LSTCOD-` to restrict the listing of output code to just the first line of code for a source line.

The default setting is `LSTCOD+`, which lists more than one line of code for a source line, if needed; i.e. long ASCII strings will produce several lines of output. Code generation is *not* affected.

### Controlling the listing of macros

Use `LSTEXP-` to disable the listing of macro-generated lines. The default is `LSTEXP+`, which lists all macro-generated lines.

Use `LSTMAC+` to list macro definitions. The default is `LSTMAC-`, which disables the listing of macro definitions.

### Controlling the listing of generated lines

Use `LSTREP-` to turn off the listing of lines generated by the directives `REPT`, `REPTC`, and `REPTI`.

The default is `LSTREP+`, which lists the generated lines.

### Generating a cross-reference table

Use `LSTXRF+` to generate a cross-reference table at the end of the assembler list for the current module. The table shows values and line numbers, and the type of the symbol.

The default is `LSTXRF-`, which does not give a cross-reference table.

## Specifying the list file format

Use `COL` to set the number of columns per page of the assembler list. The default number of columns is 80.

Use `PAGSIZ` to set the number of printed lines per page of the assembler list. The default number of lines per page is 44.

Use `LSTPAG+` to format the assembler output list into pages.

The default is `LSTPAG-`, which gives a continuous listing.

Use `PAGE` to generate a new page in the assembler list file if paging is active.

## EXAMPLES

### Turning the listing on or off

To disable the listing of a debugged section of program:

```
LSTOUT-
; Debugged section
LSTOUT+
; Not yet debugged
```

### Listing conditional code and strings

The following example shows how `LSTCND+` hides a call to a subroutine that is disabled by an `IF` directive:

```
MACRO    mac
        LSTCND+
        IF _args == 2
            DW    \0 + \1
        ELSE
            DW    \0
        ENENDIF
    ENDMAC

RSEG    DIP_CODE

mac    <2,2>
mac    2,2

END
```

This will generate the following listing:

```

9          0000
10         0000
11         0000          RSEG    DIP_CODE
12         0000
13         0000          mac     <2,2>
13.1       0000          LSTCND+
13.2       0000          IF _args == 2
13.3       0000          ELSE
13.4       0000 02000200          DW    2,2
13.5       0004          ENDF
13.6       0004          ENDMAC
14         0004          mac     2,2
14.1       0004          LSTCND+
14.2       0004          IF _args == 2
14.3       0004 0400          DW    2 + 2
14.4       0006          ELSE
14.5       0006          ENDMAC
15         0006
16         0006          END

```

The following example shows the effect of LSTCOD- and LSTCOD+ on the generated code:

```

1          0000          ASEG
2          0000
3          0000          LSTCOD-
4          0000 01000A00*    DW    1,10,100,1000,10000
5          000A          LSTCOD+
6          000A 01000A00    DW    1,10,100,1000,10000
          6400E803 1027
7          0014
8          0014          END

```

**Note:** An asterisk (\*) indicates that the line has been truncated.

### Controlling the listing of macros

The following example shows the effect of LSTEXP:

```

LSTEXP-
MACRO power_pins_high // no use of incoming argument
P_EN          // make sure that power pins are enabled
P_LDH    0xFF // set all pins high
ENDMAC          // end of macro

MACRO power_pins_low // no use of incoming argument

```

```

P_EN          // make sure that power pins are enabled
P_LDH 0x00    // set all pins low
ENDMAC        // end of macro

```

The macros are defined in the file `macros.s44` which is called from the following program:

```

RSEG  DIP_CODE

#include "macros.s44"

      WT      0x04
      JMP     init
      power_pins_high
      JMP     mute
      BR      QUIT

mute   A_RCV36
      RTN

init   A_NORM
      RTN

QUIT   WNT      0x01
      END

```

This will produce the following output without expansion of the `power_pins_high` macro:

```

1      0000          RSEG  DIP_CODE
2      0002
3      0002
4      0002          #include "macros.s44"
5      0002
6      4 0002 0904          WT      0x04

7      7 0004 ....          JMP     init
8      0006          power_pins_high
9      12 000A ....          JMP     mute
10     0 000C ....          BR      QUIT
11     000E

12     1 000E 8200  mute   A_RCV36
13     2 0010 0400          RTN
14     0012

15     1 0012 C500  init   A_NORM
16     2 0014 0400          RTN
17     0016

```

```

18      14 0016 0801      QUIT      WNT      0x01
19              0018                      END

```

**Note:** The second field from the left shows the cycle count. To make it easier to count the consumed cycles, the assembler has a built in cycle counter. This mechanism is automatically generated and the output is displayed in the list file. The cycle count represents the accumulated cycles so far in the program: the cycle count on the `WT` instruction, shown above, indicates that when this line is executed 4 cycles have been performed; when `JMP` is executed the count is incremented to 7 cycles.

### Formatting listed output

The following example formats the output into pages of 66 lines each with 132 columns. The `LSTPAG` directive organizes the listing into pages, starting each module on a new page. The `PAGE` directive inserts additional page breaks.

```

PAGSIZ 66 ; Page size
COL 132
LSTPAG+
...
ENDMOD
MODULE
...
PAGE
...

```

---

## C-style preprocessor directives

The following C-language preprocessor directives are available:

Directive	Description
<code>#define</code>	Assigns a value to a label.
<code>#elif</code>	Introduces a new condition in a <code>#if...#endif</code> block.
<code>#else</code>	Assembles instructions if a condition is false.
<code>#endif</code>	Ends a <code>#if</code> , <code>#ifdef</code> , or <code>#ifndef</code> block.
<code>#error</code>	Generates an error.
<code>#if</code>	Assembles instructions if a condition is true.
<code>#ifdef</code>	Assembles instructions if a symbol is defined.
<code>#ifndef</code>	Assembles instructions if a symbol is undefined.
<code>#include</code>	Includes a file.

*Table 23: C-style preprocessor directives*

Directive	Description
#message	Generates a message on standard output.
#undef	Undefines a label.

Table 23: C-style preprocessor directives (Continued)

## SYNTAX

```
#define label text
#elif condition
#else
#endif
#error "message"
#if condition
#ifdef label
#ifndef label
#include {"filename" | <filename>}
#message "message"
#undef label
```

## PARAMETERS

<i>condition</i>	One of the following:	
	An absolute expression	The expression must not contain forward or external references, and any non-zero value is considered as true.
	<i>string1=string</i>	The condition is true if <i>string1</i> and <i>string2</i> have the same length and contents.
	<i>string1&lt;&gt;string2</i>	The condition is true if <i>string1</i> and <i>string2</i> have different length or contents.
<i>filename</i>	Name of file to be included.	
<i>label</i>	Symbol to be defined, undefined, or tested.	
<i>message</i>	Text to be displayed.	

*text*                    Value to be assigned.

## DESCRIPTION

### Defining and undefining labels

Use `#define` to define a temporary label.

```
#define label value
```

is similar to:

```
label VAR value
```

Use `#undef` to undefine a label; the effect is as if it had not been defined.

### Conditional directives

Use the `#if...#else...#endif` directives to control the assembly process at assembly time. If the condition following the `#if` directive is not true, the subsequent instructions will not generate any code (i.e. it will not be assembled or syntax checked) until a `#endif` or `#else` directive is found.

All assembler directives (except for `END`) and file inclusion may be disabled by the conditional directives. Each `#if` directive must be terminated by a `#endif` directive. The `#else` directive is optional and, if used, it must be inside a `#if...#endif` block.

`#if...#endif` and `#if...#else...#endif` blocks may be nested to any level.

Use `#ifdef` to assemble instructions up to the next `#else` or `#endif` directive only if a symbol is defined.

Use `#ifndef` to assemble instructions up to the next `#else` or `#endif` directive only if a symbol is undefined.

### Including source files

Use `#include` to insert the contents of a file into the source file at a specified point.

`#include "filename"` searches the following directories in the specified order:

- 1 The source file directory.
- 2 The directories specified by the `-I` option, or options.
- 3 The current directory.

`#include <filename>` searches the following directories in the specified order:

- 1 The directories specified by the `-I` option, or options.
- 2 The current directory.

## Displaying errors

Use `#error` to force the assembler to generate an error, such as in a user-defined test.

## Defining comments

Use `/* ... */` to comment sections of the assembler listing.

Use `//` to mark the rest of the line as comment.

**Note:** It is important to avoid mixing the assembler language with the C-style preprocessor directives. Conceptually, they are different languages and mixing them may lead to unexpected behavior since an assembler directive is not necessarily accepted as a part of the C language.

The following example illustrates some problems that may occur when assembler comments are used in the C-style preprocessor:

```
#define version 13    ; API version

    ASEG
    DW    version    ; Expands to "DW 13 ; API version"

    DW    version + 1 ; Expands to "DW 13 ; API version + 1"
                        ; So memory will contain 13 and not
                        ; 13+1 since '+ 1' is commented away
```

## EXAMPLES

### Using conditional directives

The following example defines a label `deriv`, and then uses the conditional directive `#ifdef` to use the value if it is defined. If it is not defined `#error` displays an error:

```
#define deriv 14428

#ifdef deriv
current DW    deriv
#else
#error "'deriv' not defined"
#endif

    END
```

### Including a source file

The following example uses `#include` to include a file defining macros into the source file. For example, the following macros are defined in `macros.s44`:

```

MACRO power_pins_high // no use of incoming argument
    P_EN               // make sure that power pins are enabled
    P_LDH    0xFF      // set all pins high
    ENDMAC             // end of macro

MACRO power_pins_low  // no use of incoming argument
    P_EN               // make sure that power pins are enabled
    P_LDH    0x00      // set all pins low
    ENDMAC             // end of macro

```

The macro definitions can then be included, using `#include`, as in the following example:

```

        ASEG
        ORG      0x02

#include "macros.s44"

        WT      0x04
        JMP      init
        power_pins_high
        JMP      mute
        BR       QUIT

mute    A_RCV36
        RTN

init    A_NORM
        RTN

QUIT   WNT      0x01
        END

```

---

## Data definition or allocation directives

These directives define temporary values or reserve memory.

Directive	Description
DC8, DB	Generates 8-bit byte constants, including strings.
DC16, DW	Generates 16-bit word constants, including strings.
DQ15	Generates 16-bit fixed-point constants.
DS8, DS	Allocates space for 8-bit bytes.
DS16	Allocates space for 16-bit words.

*Table 24: Data definition or allocation directives*

## SYNTAX

```

DB expr
DC8 expr [,expr] ...
DC16 expr [,expr] ...
DQ15 value [,value] ...
DS expr [,expr]
DS8 expr [,expr] ...
DS16 expr [,expr] ...
DW expr [,expr]

```

## PARAMETERS

*expr*            A valid absolute, relocatable, or external expression, or an ASCII string. ASCII strings will be zero filled to a multiple of the size. Double-quoted strings will be zero terminated.

*value*           A valid absolute expression or a floating-point constant.

## DESCRIPTION

Use DB, DC8, DC16, DQ15, or DW to reserve and initialize memory space.

Use DS, DS8, or DS16 to reserve uninitialized memory space.

## EXAMPLES

### Defining strings

To define a string:

```
myMsg    DC8 'Please enter your name'
```

To define a string which includes a trailing zero:

```
myCstr   DC8 "This is a string."
```

To include a single quote in a string, enter it twice; for example:

```
errMsg DC8 'Don''t understand!'
```

### Reserving space

To reserve space for 0xA bytes:

```
table DS8 0xA
```

---

## Assembler control directives

These directives provide control over the operation of the assembler.

Directive	Description
\$	Includes a file.
<i>/*comment*/</i>	C-style comment delimiter.
<i>//</i>	C++-style comment delimiter.
CASEOFF	Disables case sensitivity.
CASEON	Enables case sensitivity.
RADIX	Sets the default base.

Table 25: Assembler control directives

### SYNTAX

```
$filename
/*comment*/
//comment
CASEOFF
CASEON
RADIX expr
```

### PARAMETERS

<i>comment</i>	Comment ignored by the assembler.
<i>expr</i>	Default base; default 10 (decimal).
<i>filename</i>	Name of file to be included. The \$ character must be the first character on the line.

### DESCRIPTION

Use \$ to insert the contents of a file into the source file at a specified point.

Use `/* . . . */` to comment sections of the assembler listing.

Use `//` to mark the rest of the line as comment.

Use `RADIX` to set the default base for use in conversion of constants from ASCII source to the internal binary format.

To change the base from 16 to 10, `expr` can be written in hexadecimal format, for example:

```
RADIX D'10
```

### Controlling case sensitivity

Use `CASEON` or `CASEOFF` to turn on or off case sensitivity for user-defined symbols. By default case sensitivity is off.

When `CASEOFF` is active all symbols are stored in upper case, and all symbols used by `XLINK` should be written in upper case in the `XLINK` definition file.

## EXAMPLES

### Including a source file

The following example uses `$` to include a file defining macros into the source file. For example, the following macros could be defined in `mymacros.s44`:

```
MACRO power_pins_high // no use of incoming argument
    P_EN                // make sure that power pins are enabled
    P_LDH    0xFF      // set all pins high
    ENDMAC              // end of macro

MACRO power_pins_low  // no use of incoming argument
    P_EN                // make sure that power pins are enabled
    P_LDH    0x00      // set all pins low
    ENDMAC              // end of macro
```

The macro definitions can be included with a `$` directive, as in:

```
RSEG    DIP_CODE

$include "mymacros.s44"

WT      0x04
JMP     init
power_pins_high
JMP     mute
BR      QUIT
```

```

mute    A_RCV36
        RTN

init    A_NORM
        RTN

QUIT    WNT    0x01
        END

```

### Defining comments

The following example shows how `/* . . . */` can be used for a multi-line comment:

```

/*
Program to read serial input.
Version 3: dd.mm.yy
Author: mjp
*/

```

### Changing the base

To set the default base to 16:

```

RADIX  D'16
WT     A,12

```

The immediate argument will then be interpreted as H'12.

### Controlling case sensitivity

When `CASEOFF` is set, `label` and `LABEL` are identical in the following example:

```

label  WNT 0x01          ;stored as "LABEL"
      JMP LABEL

```

The following will generate a duplicate label error:

```

label  WNT 0x01
LABEL  WNT 0x01          ;Error: "LABEL" already defined
      END

```

# Assembler diagnostics

This chapter describes the format of the diagnostic messages and explains how diagnostic messages are divided into different levels of severity.

---

## Message format

All diagnostic messages are issued as complete, self-explanatory messages. A typical diagnostic message from the assembler is produced in the form:

```
filename,linenumber level[tag]: message
```

where *filename* is the name of the source file in which the error was encountered; *linenumber* is the line number at which the assembler detected the error; *level* is the level of seriousness of the diagnostic; *tag* is a unique tag that identifies the diagnostic message; *message* is a self-explanatory message, possibly several lines long.

Diagnostic messages are displayed on the screen, as well as printed in the optional list file.

---

## Severity levels

The diagnostic messages produced by the SC14 IAR Assembler reflect problems or errors that are found in the source code or occur at assembly time.

### **ASSEMBLY WARNING MESSAGES**

Assembly warning messages are produced when the assembler has found a construct which is probably the result of a programming error or omission.

### **COMMAND LINE ERROR MESSAGES**

Command line errors occur when the assembler is invoked with incorrect parameters. The most common situation is when a file cannot be opened, or with duplicate, misspelled, or missing command line options.

### **ASSEMBLY ERROR MESSAGES**

Assembly error messages are produced when the assembler has found a construct which violates the language rules.

### **ASSEMBLY FATAL ERROR MESSAGES**

Assembly fatal error messages are produced when the assembler has found a user error so severe that further processing is not considered meaningful. After the diagnostic message has been issued the assembly is immediately terminated.

## **ASSEMBLER INTERNAL ERROR MESSAGES**

During assembly a number of internal consistency checks are performed and if any of these checks fail, the assembler will terminate after giving a short description of the problem. Such errors should normally not occur. However, if you should encounter an error of this type, please report it to your software distributor or to IAR Technical Support. Please include information enough to reproduce the problem. This would typically include:

- The exact internal error message text.
- The source file of the program that generated the internal error.
- A list of the options that were used when the internal error occurred.
- The version number of the assembler, which can be seen in the header of the list files generated by the assembler.
